

## D Postering

All the buildings in the east district of Byteburg were built in accordance with the old architecture: they stand next to each other with no spacing inbetween. Together they form a very long chain of buildings of diverse height, extending from east to west.

The mayor of Byteburg, Byteasar, has decided to have the north face of the chain covered with posters. Byteasar ponders over the minimum number of posters sufficient to cover the whole north face. The posters have rectangular shape with vertical and horizontal sides. They cannot overlap, but may touch each other, i.e. have common points on the sides. Every poster has to entirely adjoin the walls of certain buildings and the whole surface of the north face has to be covered.

### Súťažná úloha

Write a programme that:

reads the description of buildings from the standard input,

determines the minimum number of posters needed to entirely cover their north faces,

writes out the outcome to the standard output.

### Formát vstupu

The first line of the standard input contains one integer  $N$  ( $1 \leq N \leq 250\,000$ ), denoting the number of buildings the chain comprises of. Each of the following lines contains two integers  $D_i$  and  $W_i$  ( $1 \leq D_i, W_i \leq 1,000\,000\,000$ ), separated by a single space, denoting respectively the length and height of the  $i$ -th building in the row.

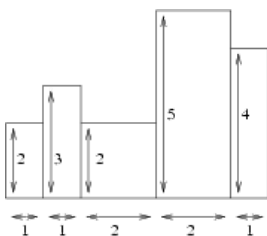

### Formát výstupu

The output consists of  $T$  lines.  $i$ -th line contains one integer, the minimum number of rectangular posters that suffice to cover the north faces of the buildings in  $i$ -th case.

### Príklad

vstup

```
